

# Chasing the Unicorn: RHIC and the QGP

Unicorn = fantastic and mythical beast!

RHIC = Relativistic Heavy Ion Collider @ Brookhaven Natl. Lab (BNL):  
collide large nuclei at high energies (also: SPS & LHC @ CERN)

QGP = Quark Gluon Plasma =  
New *state* of hadronic matter, in  
thermodynamic *equilibrium* at temperature  $T \neq 0$

*Q: Has RHIC made the QGP?*

1. QCD @ nonzero temperature: what is the QGP?
2. The QGP on the Lattice: numerical “experiment”
3. “Gluon Stuff” @ RHIC:  
the (high-pt) tail wags the (low-pt) body of the Unicorn

*A: Some new kind of matter has been created*

# QCD at nonzero temperature: restoration of chiral symmetry

Like a magnet: *broken* at low temperature,  
*restored* at some finite temperature.

up & down quarks: “flavor” symmetry =  $SU_L(2) \times SU_R(2) = O(4)$

with strange:  $SU_L(3) \times SU_R(3)$

In broken phase, (approx.) “spin waves”  
= (almost massless) pions, K’s,  $\eta$

(What about  $\eta'$  from extra axial U(1)? Instantons....

Could dramatically affect transition properties with *light* quarks.)

# Deconfinement as a *Global* $Z(3)$ Symmetry

Multiply each quark by a **constant** phase:

$$q \rightarrow e^{2\pi i/3} q \quad , \quad \bar{q} \rightarrow e^{-2\pi i/3} \bar{q}$$

Mesons and baryons don't change:

$$\bar{q}q \rightarrow \bar{q}q \quad , \quad qqq \rightarrow (e^{2\pi i/3})^3 qqq = qqq$$

but  $q$ ,  $qq$ , etc, do not. Could use  $\exp(-2\pi i/3)$ , too =  $Z(3)$  symmetry.

$Z(3)$  spin = *Polyakov loop*  
= *propagator* “test” quark =>

$$\ell = \frac{1}{3} \text{tr } \mathcal{P} \exp \left( ig \int_0^{1/T} A_0 d\tau \right)$$

= (trace) color Aharonov-Bohm phase.

$g$  = QCD coupling constant. For small  $g$ , loop  $\sim 1$ .

Only valid in a **pure** gauge theory, with**out** dynamical quarks.

In QCD, is the  $Z(3)$  symmetry **approximate**?

# Deconfinement & Polyakov Loops

't Hooft: part of *local* SU(3) is *global* Z(3)  $\ell \rightarrow e^{2\pi i/3} \ell$

At T=0, confinement => quarks don't propagate => UNbroken Z(3) symmetry

$$\langle \ell \rangle = 0 \quad , \quad T < T_{deconf}$$

As  $T \rightarrow \infty$ , by *asymptotic freedom*,  $g^2$  small, pert. thy. ok, => loop is near one (times Z(3) phase).

=> deconfined phase in which quarks propagate:

$$\langle \ell \rangle \neq 0 \quad , \quad T > T_{deconf}$$

Deconfinement *opposite* to spins:

Z(3) broken at *high*, and not *low*, temp.

# Order of Phase Transitions

Relation between deconfining and chiral transitions? 1 or 2 trans.'s?

For QCD, both  $Z(3)$  and chiral symmetries are *approximate*.

*Strongly First Order Transition(s)?*

“Of course”! Hadrons  $\neq$  Quarks & Gluons.

Limits:

Deconfining transition (NO quarks): cubic invariant is  $Z(3)$  symmetric:  $\ell^3$   
*first order deconfining trans.* (Svetitsky & Yaffe).  
# colors  $\Rightarrow \infty$ : *first order* deconf.'g trans.

Chiral transition: two massless flavors:  $O(4)$  sym.  $\Rightarrow$  *second order chiral trans.*  
three massless flavors: cubic invariant  $\det(\Phi) \Rightarrow$  *first order chiral trans.*  
if axial  $U(1)$  restored: *first order chiral transition* for 2 & 3 flavors  
(RDP & Wilczek)

The “Unicorn”:

*Quark-Gluon Plasma =*

Deconfined,  
Chirally Symmetric “Phase”  
at nonzero temperature

But how to compute  
properties of the QGP?

# QGP on the Lattice

Lattice: compute from *first* principles as lattice spacing  $a \Rightarrow 0$ . 2004:

Only gluons (no qks, pure gauge): present methods close to  $a=0$ !

$$T_d \sim 270 \pm 10 \text{ MeV}$$

Weakly first order deconfining trans. (Some masses  $\downarrow$  by  $\sim 10$ ).

Non-perturbative QGP from  $T_d \Rightarrow 3 T_d$ . No “of course”

QCD: present methods *not* close to  $a=0$ . All results tentative.

$$T_c \sim 175 \pm ? \text{ MeV}$$

Only *one* transition (chiral = deconfining)

Order? ‘04: crossover.

“Flavor independence”: pressure *with* qks  $\sim$  *without* qks.

# Lattice: pressure vs temp., pure glue to QCD

$p(T)$ =pressure. Asymptotic freedom  $\Rightarrow p/T^4 = \text{const. as } T \rightarrow \infty$

Pure glue:  $\uparrow T_c \sim 270$ . 1st order phase transition

2+1 fl's = QCD:  $\uparrow T_c \sim 175$ . No phase transition: "crossover"

# Lattice: “Flavor Independence”

Lattice finds *amazing* property:  
properly scaled, pressure *with* quarks  
like that *without*: *Bielefeld*.

$$\frac{p}{p_{ideal}} \left( \frac{T}{T_c} \right) \approx universal$$

=> pressure  
dominated by  
gluons?

# Non-pert. QGP for $T_c \Rightarrow \sim 3 T_c$

Ren.'d Polyakov loop **with** qks  $\sim$  as pure gauge  $\Rightarrow$  dominated by gluons?

Pert. thy: loop near one. Loop far from one: *non-pert. regime*.

# Early universe @ $\sim \mu\text{sec}$ : QCD phase transition

In AA collisions, *rapid expansion*.

Not sensitive to (weakly) 1st order transition, indicated by lattice.

In early universe, *slow expansion*.

Sensitivity of nucleosynthesis to 1st order trans?

Goal for lattice: order of the QCD phase trans.

'04: crossover. '08?

# The QGP Exists!

## Hunting for the “Unicorn” in Heavy Ion Collisions

“Unicorn” & the QGP: Scott, Stock, Gyulassy...

Hunters = experimentalists, “all theorists are dogs...”

# Why do AA? Big transverse size.

One can collide:

**pp**: protons on protons. Benchmark for “ordinary” strong int.’s

**AA**: nucleus with **atomic number A** on same.

**dA**: deuteron (N+P) on nucleus. Serves as another check.

**Why AA?** Baryons are like hard spheres, **so nuclear size**  $\sim A^{1/3}$

Biggest: **Pb** (lead) or **Au** (gold), **A**  $\sim 200 \Rightarrow r_A \sim 7$ .

**Transverse radius of nucleus**  $\sim A^{2/3} \Rightarrow$  trans. size  $\sim 50 \times$  proton.

**A**  $\sim 200$  close to **A**  $\rightarrow \infty =$  *infinite* nuclear matter?

# AA collisions at high energy: where?

Basic invariant: total energy in the center of mass,  $E_{c.m.} \equiv \sqrt{s}$

For AA collisions, energy *per* nucleon is  $\sqrt{s}/A \equiv \sqrt{s_{NN}}$

Machines

$$\sqrt{s}/A$$

SPS @ CERN

5 => 17 GeV

fixed target

\*\*\*\* RHIC @ BNL

20, 130, 200 GeV

collider, > 2000

LHC @ CERN

5500 GeV = 5.5 TeV

collider, > 2007

SIS200 @ GSI

2 => 6 GeV

fixed target, > 2010

SPS = Super Proton Synchrotron: CERN @ Geneva, Switzerland.

RHIC = Relativistic Heavy Ion Collider: BNL @ Long Island, NY.

LHC = Large Hadron Collider.

SIS = SchwerionenSynchrotron: GSI @ Darmstadt, Germany.

# Essentials of AA collisions

At energies  $\gg$  mass, nuclei *slam* through each other.

Particles very different *along* beam direction, vs. *transverse* to beam.

In collider: *ignore* along beam; look *just* perpendicular to beam

”central” or zero rapidity (rapidity  $\sim$  velocity along beam.)

$90^\circ$  to beam  $\Rightarrow$  few baryons  $\Rightarrow$  most likely to see nonzero temp.

Consider distribution of particles *only* in transverse momentum,  $p_t$   
Most particles at  $p_t = 0$ , fall off with increasing  $p_t$ . Thermal?

Central:  
Maximum  
Overlap

Peripheral  $\Rightarrow$   
“Almond” of  
overlap region

# Typical Heavy Ion Event @ RHIC

Experiments @ RHIC:

“Big” expts: ~ 400 people  
STAR & PHENIX

“Small” expts.: ~ 50 people  
PHOBOS & BRAHMS

Note: total # particles ~  
total # experimentalists  
~  $\log(\text{total energy})$

# theorists  
~  $\log(\log(\text{total energy}))$ .

Need hunters more than dogs...

Total # particles(/unit rapidity)  
~ 900↓

# Particle Distributions vs $\eta$ , Energy: “Central Plateau” @ RHIC

No big changes in overall multiplicity

# Why do AA? “Saturation” as a Lorentz Boost

At high energies, incident nucleus is *Lorentz contracted*.  
=> color charge of incident nucleus gets “squashed”.

McLerran & Venugopalan: color charge bigger by  $A^{1/3}$

$A \rightarrow \infty$  : can use *semi-classical* methods.

@ central rapidity, *gluon saturation* = **Color Glass**.

As semi-classical, predicts *logarithmic* growth in multiplicity:

$$\frac{dN}{dy} \sim \frac{1}{g^2(\sqrt{s}/A)} \sim \log(\sqrt{s}/A)$$

First surprise from Day 1: NO big increase in multiplicity. Approx. log growth.

Also: expect avg. momentum to grow similarly  $\langle p_t \rangle \sim \log(\sqrt{s}/A)$   
(Krasnitz & Venugopalan)

# Slow Growth in Multiplicity with Energy

Good fits to overall multiplicity, centrality dependence (Kharzeev, Levin, Nardi)

STAR: from 130  $\Rightarrow$  200 GeV, multiplicity increases by 14%,  
but NO change in  $\langle p_t \rangle \pm 2\%$ . Vs.  $> 7\%$  increase from Color Glass!

# Body of the “Unicorn”:

Majority of particles, at small momenta  
 $< 2 \text{ GeV}$ .

# Tail of the “Unicorn”:

Look at particles at *HIGH* momentum,  
 $p_t > 2 \text{ GeV}$ , to probe the body.

The Tail wags the (Dog) Unicorn

# Tail Wags the Dog $\neq$ “Wag the Dog”

DUSTIN  
**HOFFMAN**

ROBERT  
**DE NIRO**

In central AA @ RHIC,  
there IS “gluon stuff”

Still no WMD’s...

A Hollywood producer.

A Washington spin-doctor.

When they get together,  
they can make you  
believe anything.

# Jets: “seeing” quarks and gluons in QCD

2 jets from pp collision:

STAR @ RHIC

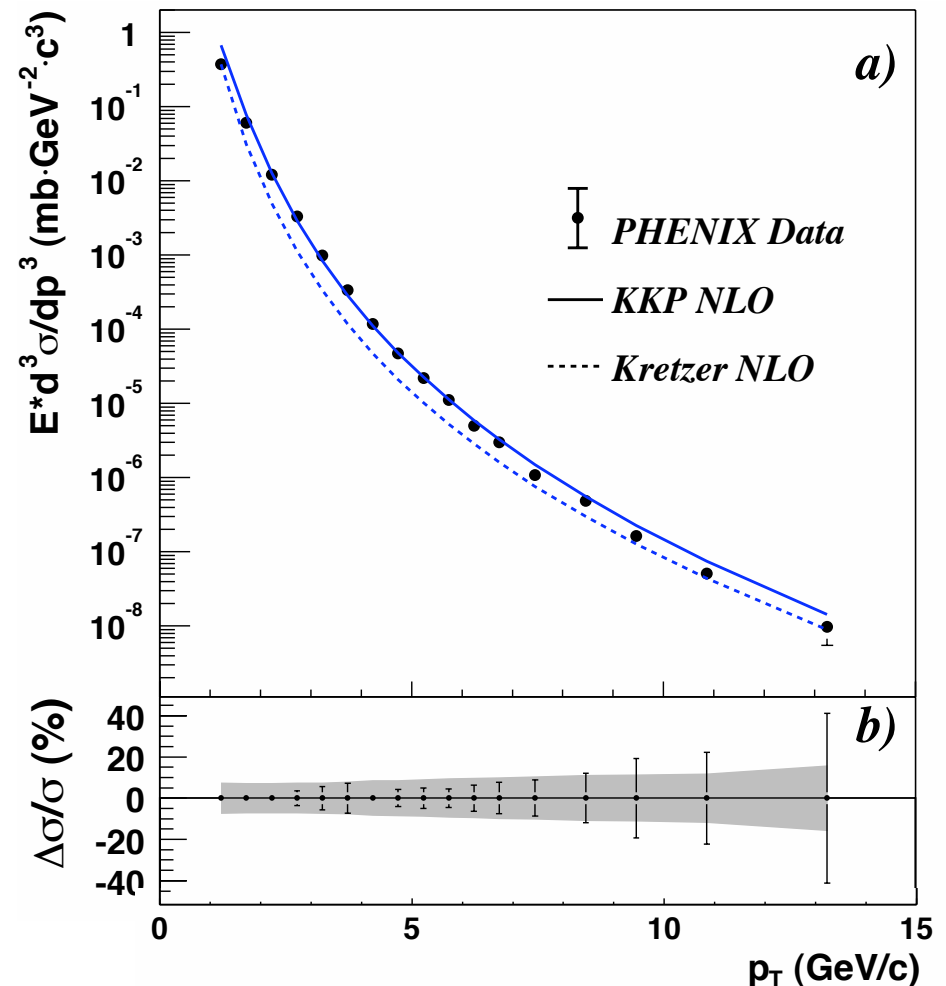

Quarks & gluons => *jets*.

<= jets in pp @ RHIC.

For each jet, there is a backward jet.

Jets can be computed at high energy in pert. thy., down to ---  
50 GeV? 5 GeV?

Vogelsang et al =>

# “Jets” in central AA collisions

pp collisions:  $\sim 4$  particles/unit rapidity, vs 900 in central AA.  
Hence hard to see *individual* jets in AA.

Can construct statistical measures.

$p_t$  = momentum transverse to beam

Trigger on “hard” particle,  
 $p_t: 4 \Rightarrow 6$  GeV

Given a jet in one direction,  
there *must* be *something* in the  
opposite direction.

Look for the “away” side jet,  $p_t > 2$  GeV. (mass proton  $\sim 1$  GeV)

# Central AA collisions “eat” jets!

In pp or dAu collisions, *clearly* see away side jet.

In central Au-Au, away side jet gone: “stuff” in central AA “eats” jets!

Fast jet tends to lose energy by many soft scatterings off “stuff”.

Adams *et al.*, Phys. Rev. Let. 91 (2003)

# Peripheral Coll's: Geometrical Test that AA Eats Jets

Peripheral collisions, “stuff” forms “almond”: a jet travels farther through the almond, **out** of the reaction plane, than **in** the plane.

Exp.'y: backward jet more strongly suppressed **out** of plane than **in** plane => **geometrical** test that central AA “**eats**” jets

STAR preliminary

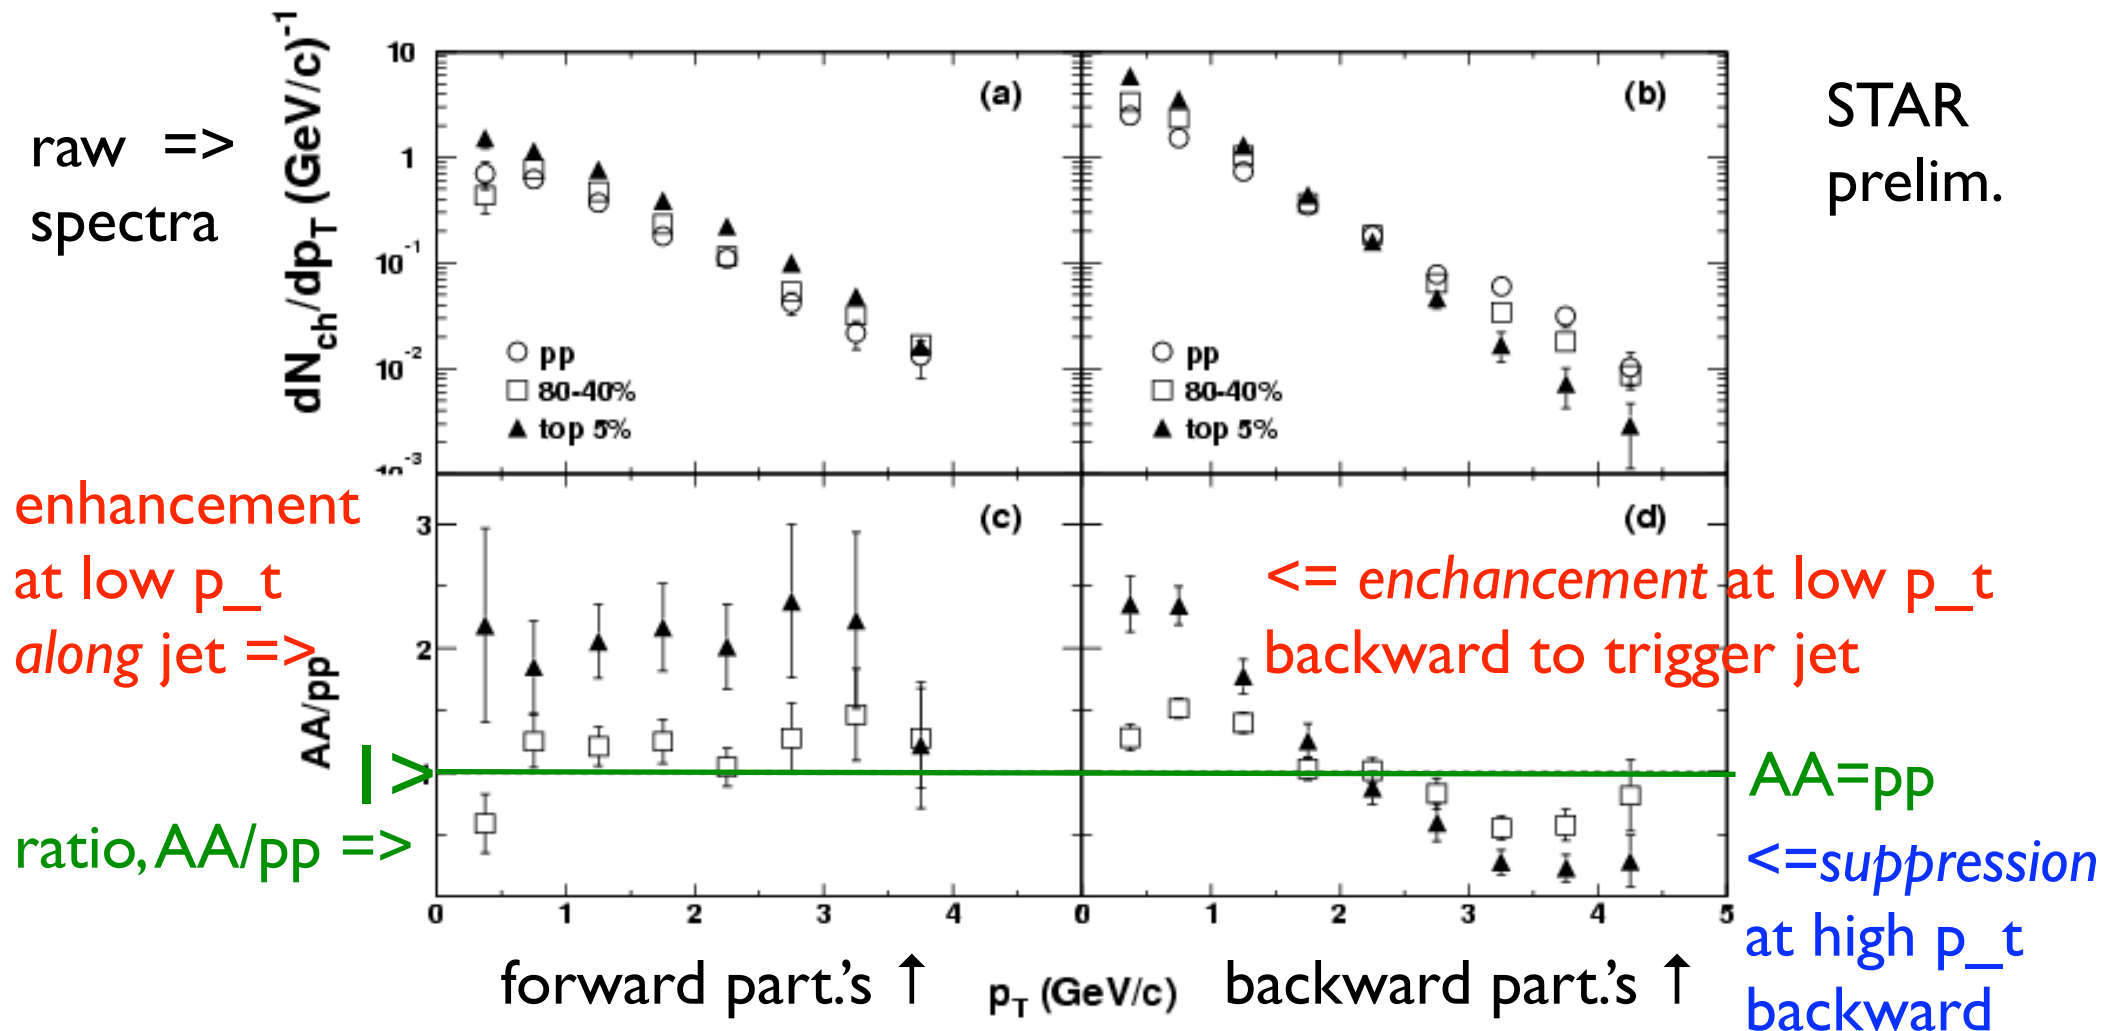

# Central AA: high $p_t$ jets give low $p_t$ remains!

Trigger on all particles,  $p_t > .15$  GeV.

Backward jet: high  $p_t$  suppressed, low  $p_t$  enhanced.

“Stuff” in central AA slows fast particle down.

Forward jet: enhanced at low momentum: “stuff” dragged along!

# Clear Experimental Signal of “Stuff”: $R_{AA}$

Compare *central* AA spectra to pp spectra, esp. “hard”  $p_t > 2$  GeV:

$R_{AA} = \# \text{ particles at a given } p_t, \text{ in central AA collision} /$   
 $(\# \text{ part's at the same } p_t \text{ in pp, central rapidity} \times A^{\{4/3\}})$

$R_{AA} \Rightarrow$   
suppression of  
hard particles  
in AA, vs pp.

$p_t > 6$  GeV,  
~ constant  
suppression.

# R\_AA: Enhancement @ SPS, Suppression @ RHIC

Effect most dramatic for  $\pi^0$ 's. SPS:  $R_{AA} \sim 2.5$  @ 3 GeV. “Cronin”

RHIC:  $R_{AA} \sim 0.2$  @ 3 GeV.

RHIC: Supp. from energy loss - “stuff” slows fast particles down.

# $R_{AA}$ final state effect: not seen in $R_{dA}$

$R_{dA}$ : like  $R_{AA}$ , but for dA/pp. *Central rapidity ( $y=0$ ):*

“Cronin” enhancement in dA, vs suppression in AA.

NO “color glass” suppression. McLerran, Venugopalan, Kharzeev, Iancu...

AA=>

Suppression in AA  $\uparrow$   
 $R_{AA} \sim 0.4$  @ 3 GeV

<=dA

Enhancement in dA  $\uparrow$   
 $R_{dA} \sim 1.4$  @ 3 GeV

# R\_AA: Qualitative Agreement with “Energy Loss”

**Energy Loss:** A fast particle going through a thermal bath loses energy:

Landau, Pomeranchuk, Migdal '50's  
Gyulassy, X.N. Wang, Vitev...Baier,  
Dokshitzer, Mueller, Schiff, Zakharov

$\leq$  Gyulassy & Vitev: *conspiracy*  
to give *flat*  $R_{AA}$  @ RHIC.

Need to add “Cronin”, shadowing...

Is “flat”  $R_{AA}$  for  $\pi^0$ 's special  
to RHIC? Will be interesting  
@ LHC!

*When does  $R_{AA} \Rightarrow 1$ ?*

# Where to find the Color Glass: dA, by the *proton*

Fragmentation region: like looking in the rest frame.

Incident projectile gets Lorentz contracted:

proton fragmentation  
region

nuclear fragmentation  
region

Nuclear frag. region: proton contracted. Study *final* state effects

Proton frag. region: study *initial* state effects

(Dumitru & Jalilian-Marian, Gelis...)

Scatter valence quarks off classical (gluon) field  $\Rightarrow \pi^+/\pi^-$  asymmetry

# dA, by the proton: *suppresion!*

BRAHMS in dA, *enhancement* @ central rapidity (per. to beam)  
*suppression* @ proton frag. region. (along beam)

Supports color glass initial state.

# Central AA: at $p_t \geq 6$ GeV, no baryon supp.

$R_{CP}$ : ratio for # particles at given  $p_t$ , for central to peripheral collisions

Behaves like  $R_{AA}$ , easier to get data.

Find: *baryons* not suppressed for  $p_t \geq 6$  GeV, *mesons* are.

Mesons suppressed  $\Rightarrow$  “stuff” is gluonic.

$R_{CP} \uparrow$

# Baryon “Bump” at $p_T: 2 \Rightarrow 6$ GeV

Central AA: *baryon “bump” at  $p_T: 2 \Rightarrow 6$  GeV*

Baryon/meson ratio enhanced by  $\sim 3$  in central AA vs pp. First seen in  $p/\pi$ .

$\leq \Lambda/K$  ratio: bump peaks at  $\sim 3$  GeV.

Above  $p_T = 6$  GeV, ratios like pp.

$R_{CP}$  vs particle species  $\Rightarrow$

*All particles suppressed  $> 6$  GeV,  $R_{CP} \sim 0.2$ .*

*$\Rightarrow$  Gluon “stuff” supp.’s mesons, generates baryon “bump”*

# dA: No “Cronin” Enhancement at High $p_t$

At high  $p_t$ , all R's ( $R_{AA}$  &  $R_{CP}$ ) should go to one.

In dA, seen in  $R_{CP}$  for  $p_t \sim 8$  GeV.

At what  $p_t$  does  $R_{AA} \Rightarrow 1$ ?  $> 10$  GeV!

# Direct Photons Measured

**Direct photons:** easily escape, so probe initial state. *Without* pion suppression, very hard to measure (true at SPS). *With* observed suppression of  $\pi^0$ 's, measurable. Reasonable agreement at  $p_t \sim 10$  GeV with Next to Leading Order QCD calculation, = pp times # binary collisions.

# The “body” of the unicorn: soft $p_t < 2 \text{ GeV}$

Particles peaked about zero (transverse) momentum

$T_c \sim 200 \text{ MeV}$ : expect thermal to  $p_t \sim 2 \text{ GeV}$ .

Thousands of particles, hydrodynamics should be ok...

“dog”=>

<=unicorn

# Total Chemical Ratios *Appear* in Thermal Equilibrium

$$T_{ch} = 175 \text{ MeV}$$

Braun-Munzinger et al., PLB 518 (2001) 41 D. Magestro (updated July 22, 2002)

**OVERALL** chemical abundances *well* fit with  $T_{ch} = 175 \text{ MeV}$ ,  $\mu_{\text{baryon}} \sim 0$   
 (Becattini, Braun-Munzinger, Letessier, Rafelski, Redlich, Stachel, Tounsi...)

N.B.: even for multi-strange baryons, with relative abundances  $\sim 1\%$  of pions.

# Exact critical point in plane of $T$ & $\mu$

Similar fits also work at lower energies. Need baryon chemical potential,  $\mu$ .

(Apparent)  $T_{ch}$  in pA, pp - everywhere!  $\Rightarrow$  NOT conclusive.

N.B.: in  $T$ - $\mu$  plane, expect exact critical point - GSI?

# $p_t$ Spectra *Appear* In Thermal Equi. $\sim$ *Hydrodynamics*

$T_{kin} \approx 100 \text{ MeV} (\ll T_{ch}!)$  Local Boost Velocity  $\beta \sim .7c$

Hydro. gives good description for most particles, at low  $p_t < 1 \text{ GeV}$ .

Assumes initial conditions: starts  
above  $T_c$  in thermal equilibrium, *simple*  
Equation of State (1st order!)  
*Ideal* hydro.: NO viscosity...

Large local boost velocity  $\beta \sim .7 c$ .  
Spectra of heavy particles “turn  
over” at low  $p_t$ .  $\beta = \beta(\text{radius})$ .

RHIC: *first clear evidence for  
boost velocity: big!*

Direct fits similar: “**Blast-wave**”

Hydro *needs* to assume applicable from very early times, **.6 fm/c!**

Heinz, Hirano, Kolb, Rapp, Shuryak, Teaney... (above Heinz & Kolb)

# Success of Hydro.: $v_2 =$ Elliptical Flow

Peripheral Coll.'s: Start with system which is anisotropic in momentum space. Exp.'y, compute how *spatial* anisotropy  $\Rightarrow$  *momentum* anisotropy. (Ollitrault, Borghini)

$$v_2 = \langle \cos(2\phi) \rangle, \quad \tan \phi = p_y / p_x$$

$v_2 \Rightarrow$  collective behavior:  
there is “stuff”, and it sticks.

Hydro works for  $v_2$  @ RHIC, not SPS.

# At Low $p_t < 1$ GeV, Hydro. works for All Particles

$\leq$  Hydro works for  $v_2$   
 to  $p_t \sim 1$  GeV for  
 $\pi$ 's, K's, p's,  $\Lambda$ 's.... everything.

For all particles,  $v_2$  flat for  
 $p_t > 1$  GeV  $\Rightarrow$  10 GeV - !!

Is  $v_2$  at  $p_t > 1$  GeV measuring  
 collective flow, or jet-jet correlations?  
 Apparently: true collective flow.

So why flat?

# HBT Radii: Hydro *Fails*. “Blast Wave” Works

Hanbury-Brown-Twiss: two-particle correlations for identical particles ▶

Sizes at freezeout. *Three* directions, Bertsch & Pratt:

along beam  $R_{\text{long}}$ , along line of sight  $R_{\text{out}}$ , perpendicular  $R_{\text{side}}$ .

$$C(p_1, p_2) = \frac{N(p_1, p_2)}{N(p_1)N(p_2)}$$

$$= 1 + \lambda \exp(-R^2(p_1 - p_2)^2)$$

Hydro:  $R_{\text{out}}/R_{\text{side}} > 1$ ,  
increases with  $p_{\text{t}}$ .

Exp.:  $R_{\text{out}}/R_{\text{side}} \sim 1$ ,  
decreases with  $p_{\text{t}}$ !

Hydro:  $R_{\text{long}}$ ,  $R_{\text{out}}$  too big.

Peripheral coll.'s: azimuthally Asym. HBT

# HBT radii $\sim$ same in pp, dA, and AA!

Can also measure HBT in pp, dA...

Ratios behave  $\sim$  same with  $p_t$ !

Can fit HBT radii to “blast wave”  
= *fit* not fundamental model.

Blast wave suggests:

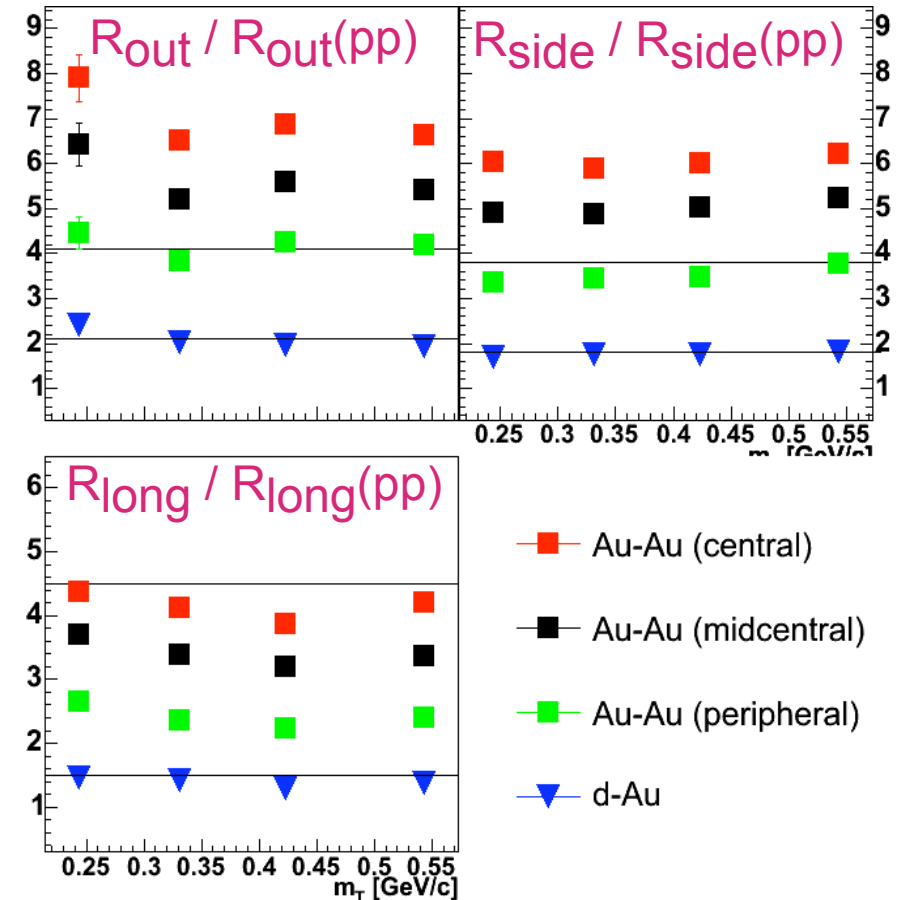

lifetime  $\sim 8-9$  fm/c, emission  $\sim 2$  fm/c

(No big times from strong 1st order!)

Space-time history “exploding shell”

HBT  $\Rightarrow$  *universal* hadronization?

Fluctuations ( $p_t$ ...) *NOT* same in  
pp, dA, AA....

$m_t \sim p_t \Rightarrow$

STAR  
prelim.

# Has RHIC found (tamed) the “Unicorn” = QGP?

New final state effects:

R\_AA

Suppression of backward jets

Also: new initial state effects,  
BRAHMS: Color Glass in forward dA

Exp.'y: for the unicorn of central AA,  
the high  $p_t$  “tail” wags the  
low  $p_t$  “body”

HBT=>universal, explosive  
hadronization?

Perhaps: it is a different beast....  
But its still a *NEW* beast!

*"A possible eureka."*
